Development of Innovative Technologies for Exploration of Deep-sea Resources

Challenge for exploration and production of deep-sea resources for future industrialization

The deep seafloor around Japan is known to contain a large amount of mineral resources. Recent studies have identified the existence of marine mineral resources, including rare earth deposits that are essential to economic and social development. They have been found at the sea bottom approximately 2,000 m to 6,000 m below the sea surface, which accounts for two-thirds of the seabed of Japan’s exclusive economic zone (EEZ). The program to be pursued through the collaboration of nine ministries aims to take a step-by-step approach to establish and verify innovative technologies for exploration of deep-sea resources, including mineral resources, such as rare earth deposits existing in the deep seafloor. The objectives are to be a global pioneer, to promote social implementation of the technologies, such as technology transfer to private corporations, and to pave the way toward the future establishment of a business model.

Profile

Graduated from Department of Economics, Faculty of Humanities, Niigata University in 1973. Joined JAPEX in the same year, Became a Director and head of Planning Department, the head of Managing Executive Officers and director of Nagaoka Mining Station, a Managing Executive Director, a Senior Managing Executive Director, the Representative Director and Vice President, and then an advisor (the present post). Assumed the post of the Representative Director and President of Japan CCS Co., Ltd. upon its establishment in 2008. Served as a member of Coordination Subcommitte, Committee on Oceanic Resources, Keidaien from 2009 till 2018. Assumed the post of the Representative Director and President of Japan Methane Hydrate Operating Co., Ltd. upon its establishment in 2014.

Program Director

Shoichi Ishii
Adviser to Japan Petroleum Exploration Co., Ltd. (JAPEX)

Research and Development Topics

1. Exploration and analysis of the abundance of marine mineral resources including rare earth deposits
   It has been reported that large deposits of rare earth minerals with a high concentration of rare earth elements (rare earth deposits) occur in the seafloor surrounding Minamitotorishima Island in the Japanese EEZ. We will narrow down sites with the greatest potential for development and make a rough estimate of the amount of rare earth minerals.

2-1. Development of technologies for exploration of deep-sea resources
   (operation of multiple Autonomous Underwater Vehicles (AUVs) and a terminal system with a battery charger in the deep sea)
   In order to estimate the accurate potential of various deep-sea resources existing at depths between 2,000 m and 6,000 m, we need to establish technologies to efficiently explore precise bathymetric features and sub-seafloor structures. For this purpose, we will attempt to build a system capable of exploring deep-sea resources with high efficiency by developing the technology for simultaneous operation of multiple deep-sea AUVs and technology concerning deep-sea terminals with a battery charger, which would enable AUVs to cruise for longer periods.

2-2. Development of technologies for production of deep-sea resources
   (cracking, sampling and lifting technology of rare earth deposits)
   A system for continuous retrieval of rare earth deposits from the bottom of the deep sea does not exist. Thus, it is necessary to establish technologies for cracking solidified rare earth deposits and for lifting the cracked deposits to the ship by fluid circulation through the drill pipes of the deep-sea drilling vessel Chikyu. We will verify the technologies for granulation, sampling and lifting through field experiments in the actual sea and establish this engineering system as a global pioneer.

3. Verification of the survey and development system for deep-sea resources
   For the purpose of paving the way toward the establishment of a business model to develop deep-sea resources, we will apply the environmental impact assessment method and comprehensively verify the engineering system developed through the research activities of Themes 1, 2-1 and 2-2. Through such verification, we will take a step-by-step approach toward future industrialization in relation to the development of deep-sea resources by gaining opportunities for deep-sea surveys in response to various needs.

Cross-ministerial Strategic Innovation Promotion Program (SIP)
Implementation Structure

The Program Director (PD) is responsible for general management of the whole project. The PD will establish appropriate vertical and horizontal linkages with theme leaders and the Management Agency and build a management scheme in cooperation with such persons. In addition, an Advisory Board, which provides advice from technical and academic points of view, is established. Furthermore, coordination scheme based on the collaboration among ministries is built in the Promotion Committee so that steady progress can be made toward the establishment of technologies for exploration of marine resources, which is important for the future of Japan.

Promotion Committee
Leader: Cabinet Office (Council for Science, Technology and Innovation), Sub leader: National Ocean Policy Secretariat (Cabinet Office), National Space Policy Secretariat (Cabinet Office), the Ministry of Internal Affairs and Communications, the Ministry of Foreign Affairs, the Ministry of Education, Culture, Sports, Science and Technology, the Ministry of Agriculture, Forestry and Fisheries, Ministry of Economy, Trade and Industry, the Ministry of Land, Infrastructure and Transport, the Ministry of Environment, the Ministry of Defense, Japan Agency for Marine-Earth Science and Technology (JAMSTEC), Japan Oil, Gas and Metals National Corporation (JOGMEC), and National Institute of Maritime, Port and Aviation Technology (NIPAT)

Exit Strategies

Establishment of a model for industrialization of deep-sea resources
Survey and retrieval technologies developed through this program will be strategically transferred to industry after verification of their practicality and effectiveness so that they may be commercially utilized. Private companies, which receive technology transfers, will win contracts for deep-sea surveys in response to various needs, thereby further activating the marine survey industry in a close industry-academia-government collaboration. In the process of technology transfer, we will define challenges to be overcome, examine methods to reduce the impact on the environment, and formulate a business model for the future development of deep-sea resources.

Expected Outcomes

Estimation of the approximate amount of rare earth deposits existing around Minamitorishima Island
The approximate amount of rare earth deposits existing around Minamitorishima Island, which are gathering attention as Japan’s valuable marine mineral resources, will be estimated.

Remarkable improvement of capabilities for exploration of deep-sea resources
Capabilities for exploration of deep-sea resources will be dramatically improved, and the most advanced exploration system in the world which will realize exploration in the sea area at the depth of 6,000m or less, which accounts for 94% of the Japanese EEZ, will be developed.

Realization of technologies for production of deep-sea resources
We will be the first in the world to establish a technology to achieve sampling and lifting of marine mineral resources, which cannot be achieved by any existing technologies.

Technology transfer to industry
As for the results of technology development, we will verify the exploration and development system with the participation of industry for the purpose of technology transfer to industry and identify future tasks and possible solutions toward industrialization.
